This tutorial shows you how to automatically put a computer system into "power save mode" after a certain period of time. Although this method is quite simple, it is considered the best approach for safe, long term power savings. This is an introduction to the chip maker's technology for understanding the technology that drives it, as well as an introduction to the core technologies it uses. The first video discusses the design of the processor, including the history of the development of the silicon. As the processor was becoming more complex, Intel began using optical lithography at 32 nm, but at 65 nm they shifted to another type of lithography known as immersion lithography. We also discuss the structure of the processor, which is designed to be scalable. Finally, we look at the organization of the processor, which is designed to be cost effective. This is a summary of the trends that Intel is currently following to build the next generation of the processor. The first aspect of this video is about the transistor structure and its manufacturing. The second focuses on the packaging and the third is about the hierarchy of the layers within the packaging. This is a summary of the technical details about the first four generations of the processor. We start with the original processor and compare its packaging, the die structure, the transistor structure and its manufacturing. Then, we look at how the original silicon was used to build the following processor. This is a summary of the technical details about the first four generations of the processor.
